Florida Retail Performance

By Joshua Smith

Project Overview

This project analyzes retail sales performance across multiple locations in Florida using SQL and Power BI. The goal of this analysis is to identify trends in sales, customer behavior, and seasonal patterns to support data-driven business decisions.

Tools Used

SQL (data extraction and joins)

Power BI (data visualization and dashboard creation)

Data Preparation

- Multiple tables were joined using SQL to create a unified dataset
- A view was created to simplify complex queries
- The dataset was then connected directly to Power BI for analysis

Key Insights

- Sales show clear seasonal patterns, increasing during warmer months
- Customer distribution is relatively balanced across demographic groups
- Miami Beach generates the highest average sales per customer
- Overall sales performance remains strong with consistent fluctuations

Business Recommendations

- Leverage seasonal trends by increasing inventory and staffing during high-demand periods
- Focus on high-performing locations such as Miami Beach for expansion strategies
- Use customer demographic insights to tailor marketing efforts

Conclusion

This dashboard demonstrates how combining SQL and Power BI can provide valuable insights into retail performance. The analysis highlights the importance of seasonal trends and location-based performance in driving business strategy.
